

Python Basics

```
In [1]: # What is your name! print your name!  
# Only use one print function  
  
print("SHAM AMBADAS JOHARI")
```

SHAM AMBADAS JOHARI

- () <= Parentheses
- ' ' <= Single Quotes
- " " <= Double Quotes
- \n <= New_line
- # <= Used to comment inside code

```
In [2]: # define variables named as with values: mukesh=7, z=6, rohan=5, Longitude=4  
  
mukesh=7  
z=6  
rohan=5  
longitude=4
```

```
In [3]: # print required variable  
# output - 5  
  
rohan
```

Out[3]: 5

Variable Assignment: **Variable_Name = Value**

Variables Naming Rules:

- Python is case-sensitive => x=5 is different from X=5 (one is lower and other is upper case)
- var name can't start with special character except underscore(_) => _X = 7 is valid, @X = 7 is invalid
- var name can't start with number => 9X = 7 is invalid, X9 = 7 is valid
- can't use keywords as a variable name *

Declaring a Variable

```
In [15]: # declare 4 variables with values as: ur_age 21,ur_weight 50.6, ur_first_name

ur_age = 21
ur_weight = 50.6
ur_first_name = 'Mukesh'
ur_last_name = "Manral"
```

Data Type(Type of variable)

Name	Type	Description
Integers	int	Integer number, like 34,-56 ...
Float	float	Decimal number, like 3.4,-5.6 ...
String	str	Ordered sequence of characters, like 'your name'
Boolean	bool	Logical values indicating True or False only

```
In [14]: # print type of ur_age,ur_weight,ur_first_name,ur_last_name variables
```

```
print(type(ur_age))
print(type(ur_weight))
print(type(ur_first_name))
print(type(ur_last_name))
```

```
<class 'int'>
<class 'float'>
<class 'str'>
<class 'str'>
```

```
In [16]: # print values of ur_age,ur_weight,ur_first_name,ur_last_name variables
```

```
print(ur_age)
print(ur_weight)
print(ur_first_name)
print(ur_last_name)
```

```
21
50.6
Mukesh
Manral
```

```
In [37]: # make 2 variables with values as: ur_first_name 'Mukesh',ur_last_name'Mukesh'

# make a variable TrueOrFalse which will have comparison of variables ur_last_

ur_first_name = 'Mukesh'
ur_last_name = 'Mukesh'

TrueOrFalse = ur_last_name == ur_first_name

TrueOrFalse
```

Out[37]: True

```
In [19]: # define a variable name "x" and assign value 777 and print it

x = 777
print(x)

777
```

- To view some data on screen, python have print function
 - Using print function we can control view on output screen

In []:

Operators : Symbols that represent mathematical or logical tasks

Example:

700 + 77

- + <= Operator
- 700 & 77 <= Operands

```
In [20]: # Initialize variables [x,y,z,zz] with values
## x as 7 =>int ,
## y as 77 =>int,
## z as 77.7 => float,
## zz as 'Hi' => string

x = 7
y = 77
z = 77.7
zz = 'Hi'
```

Arithmetic Operators

```
In [35]: # add x and z
add = x + y
add
```

Out[35]: 84

```
In [36]: # subtract z and y
sub = z - y
sub
```

Out[36]: 0.70000000000000028

```
In [38]: # Multiply x and z
mul = x * z
mul
```

Out[38]: 543.9

```
In [39]: # Exponent (raise the power or times) x times z
exp = x**z
exp
```

Out[39]: 4.614426248242042e+65

```
In [40]: # division on x and z
div = x / z
div
```

Out[40]: 0.09009009009009009

// => divides and returns integer value of quotient

- It will dump digits after decimal

```
In [42]: # floor division(ignores decimal) on x and z (gives quotient)

fdiv = x // z
fdiv
```

Out[42]: 0.0

```
In [43]: # Modulo(gives remainder) on x and z
mod = x % z
mod
```

Out[43]: 7.0

Comparison Operators

```
In [44]: # comapre and see if x is less then z  
# can use '<' symbol  
  
com = x < z  
com
```

Out[44]: True

- Bool => takes two values, either True or False

```
In [45]: # compare and see if x is less then or equall to z  
# can use '<=' symbol  
  
com1 = x <= z  
  
com1
```

Out[45]: True

```
In [50]: # comapre and see if x equall to z  
# can use '==' symbol  
  
com2 = x == z  
com2
```

Out[50]: False

```
In [51]: # comapre and see if x is greater than z  
# can use '>' symbol  
com3 = x > z  
com3
```

Out[51]: False

```
In [52]: # comapre and see if x is greater than or equall to z  
# can use '>=' symbol  
  
com4 = x >= z  
com4
```

Out[52]: False

```
In [53]: # comapre and see if x is Not equall to z  
# can use '!=' symbol  
  
com5 = x != z  
com5
```

Out[53]: True

Logical Operators

```
In [54]: # compare if 108 is equal to 108, 21 is equal to 21 using logical and
# equal to => '=='
# logical and => and

# in and both condition must be True to get a True

com6 = 108 == 108 and 21 == 21
com6
```

Out[54]: True

```
In [29]: # how above condition can give False as output show all those conditions
```

```
In [56]: # compare if 108 is equal to 108, 21 is equal to 11 using logical or
# equal to => '=='
# logical or => or

# in or Only one condition need to be True to get a True

com7 = 108 == 108 or 21 == 11
com7
```

Out[56]: True

```
In [31]: # this is for you to understand it
(108 == 108) or (21 == 11) or (108 <= 11)
```

Out[31]: True

```
In [ ]:
```

if --- else => to handle single condition

if --- elif --- else => to handle Multiple condition

Observe in Python code:

- if => statement in python
- else => statement in python
- : => colon => denotes start of if block i.e. any line written after colon belong to if condition

- => see then as indentation i.e. 4 spaces => indentation indicates all code belong to only if and then another indentation indicates code for only else block

In [57]: *# make variable with value as : money 100000*

see output of money > 2000

```
money = 100000
if money > 2000:
    print(money)
```

100000

In [58]: *# assign money variable value of 10000*

say you have this much ammount in your account

start of if condition

if money is greater then 1000 which is data science course free

if money > 1000 is false i.e. you have less money then 1000 in your account

money = 10000 # you have this much ammount in your account

```
if money > 1000:
    print(" data science course free")
else:
    print("you have less money then 1000 in your account then else will work f
```

data science course free

In [64]: *# take a test_score variable with 80 in it.*

if test_score greater then 80 then print A grade

elif test_score greater then 60 and less then 80 print B grade

else print Nothing for you

test_score = 80

```
if test_score >= 80:
    print("A grade")
elif (test_score >= 60) and (test_score < 80):
    print(" B grade")
else:
    print("Nothing for you")
```

A grade

In []:

Python Loops

```
In [39]: """  
for iterating_variable in sequence:  
    statement(s)  
"""
```

```
Out[39]: '\nfor iterating_variable in sequence:\n    statement(s)\n'
```

```
In [65]: for iterating_variable in range(10):  
        print(iterating_variable)
```

```
0  
1  
2  
3  
4  
5  
6  
7  
8  
9
```

```
In [67]: # print 'I love sports' 10 times using for loop  
  
for i in range(10):  
    print("I love sports")
```

```
I love sports  
I love sports  
I love sports  
I love sports  
I love sports  
I love sports  
I love sports  
I love sports  
I love sports  
I love sports
```

10 => stoping criteria of, for loop

- in => keyword
- sequence => on which to itterate
- : => colon , start of for loop

!= = not equall to => behaves as a stoping criteria

```
In [42]: # Syntax of while loop
        """
        while comparison:
            statements(s)
        """
```

```
Out[42]: '\nwhile comparison:\n    statements(s)\n'
```

```
In [68]: # while loop

        # save 0 in variable number

        # print till 10 using while loop

        i = 0
        while i < 11:
            print(i)
            i+=1
```

```
0
1
2
3
4
5
6
7
8
9
10
```

- Initialized variable `number = 0` and then increment it's value in each iteration
- Loop will only continue to run only if value is less than 10

Type of Jump Statements

Break Statement Continue Statement

Break Statement

```
In [70]: # example that uses break statement in a for loop

# take range(10) and print 'The number is' + value
# break when num equals 5

for i in range(10):
    print("The number is",i)
    if i==5:
        break
```

```
In [1]: # define a string variable with "We are creating next generation data science
string = "We are creating next generation data science eco-system at CollegeRa
```

```
In [2]: # Find length of string including spaces
len(string)
```

Out[2]: 72

```
In [3]: # Access characters in a string with indexing i.e string[0]
string[0]
```

Out[3]: 'W'

```
In [4]: # Access characters with negative indexing i.e string[-1]
string[-1]
```

Out[4]: 'r'

String Slicing

```
In [5]: # select string from first to 6th element i.e string[:6]
string[:6]
```

Out[5]: 'We are'

```
In [6]: # select string from 7th to negative 10th element i.e string[7:-10]
string[7:-10]
```

Out[6]: 'creating next generation data science eco-system at Col'

Count of a particular character in a string

```
In [7]: string.count("data")
```

Out[7]: 1

Count of a particular sub-string in a string

```
In [9]: string.count("s")
```

Out[9]: 3

Find a substring in string using find and index function

```
In [11]: # .find() => if present it will return starting index, not found then it will  
# .index() => if present it will return starting index, not found then it will  
  
print(string.find("s"))  
print(string.index("s"))
```

['C++ is easy to learn']

Python Functions

```
In [76]: """
def function_name():
    statement(s)
"""
```

Out[76]: '\ndef function_name():\n statement(s)\n'

```
In [58]: # define a function with welcome_message(name) and body 'Welcome to Functions'

def welcome_message(name):
    print(name, 'Welcome to Functions !!!')
```

```
In [59]: # call a function with your name
welcome_message("Sham")
```

Sham Welcome to Functions !!!

- def Keyword marking start of function
- function name to uniquely identify function
 - function naming follows same rules of writing identifiers
- parameters (arguments) to pass values to a function => totally optional
- () paranthesis
- colon (:) start of function
- documentation string (docstring) describe's what function does => totally optional
- return statement returns a value from function => totally optional
- inside colon is function definition it should always be present before function call or get an error

```
In [61]: # Write a function to add two number which are as 3 and 4
# in total variable store addition of 3 + 4
# print total variable

def add():
    total = 3 + 4
    print(total)
add()
```

7

Positional Arguments

Most arguments are identified by their position in function call

- Say `print(x,y)` will give different results from `print(y,x)`

What ever sequence is given while defining a function values must be taken in that sequence only

- Otherwise use argument name (**keyword arguments**) to take values
- We first define positional argument and then keyword arguments

```
In [7]: ## Create subtraction_function(small_number, large_number) and return differen

def subtraction_function(small_number, large_number):
    diff = large_number - small_number
    return diff
```

```
In [63]: # pass arguments in right order

subtraction_function(5, 10)
```

Out[63]: 5

```
In [64]: # always pass arguments using there name(keyword arguments) then order does no

subtraction_function(small_number = 5, large_number = 10)
```

Out[64]: 5

Scope of Variables means that part of program where we can access particular variable

- Local Variable => variables defined inside a function and can be only accessed from inside of that particular function
- Global Variable => variables defined outside a function and can be accessed throughout program

Let's define a global variable, "global_variable" outside function

- We will return its value using a function "random_function" and see that we would be able to access its value using that function also

```
In [86]: #### Observe every output from here onwards ####
# defining a global variable
global_variable = 'variable outside of function'

# defining function
def random_function():
    # accessing variable which is outside of this function
    return global_variable
```

```
In [87]: random_function()
```

Out[87]: 'variable outside of function'

See we can access the data of global variable from Inside of the Function

=> Let's see what will happen if we try to change value of global variable from Inside of the Function

```
In [88]: ##### Observe every output from here onwards #####  
# defining a global variable  
global_variable = 'variable outside of function'  
  
# defining function  
def random_function():  
    # changing value of global variable from inside of the function  
    global_variable = 'changing variable outside of function from inside of fu  
    # accessing variable which is outside of this function  
    return global_variable
```

```
In [89]: print(random_function())  
print(global_variable)
```

changing variable outside of function from inside of function
variable outside of function

```
In [1]: global_var = "Hi! I am from Global RFM team"  
  
def rfm():  
    return global_var  
  
rfm()
```

Out[1]: 'Hi! I am from Global RFM team'

```
In [2]: global_variable = 23  
  
def rfm():  
    global_variable = 25  
    return global_variable  
  
print(rfm())  
print(global_variable)
```

25
